

Customer Support Analytics Project - Findings & Recommendations

Executive Summary

This document summarizes the primary analytical findings and business recommendations derived from the customer support analytics project.

Key Findings

- Operational failures compound. CSAT declined from 4.48 (Failure Score 0) to 1.17 (Failure Score 3).
- Customer satisfaction drops sharply once handling time exceeds 50 minutes.
- No tickets with Quality Indicator scores of 95+ were reopened.
- Escalations significantly increase handling time, especially for high-complexity tickets.
- Technical Support underperformance was primarily explained by ticket complexity rather than queue inefficiency.
- Product category had limited impact on outcomes compared with operational execution factors.
- Agent experience consistently improved CSAT, SLA performance, FCR, and escalation rates.

Business Recommendations

- Implement alerts before tickets exceed 45 minutes of handling time.
- Increase focus on First Contact Resolution initiatives.
- Reduce escalation volume through coaching and knowledge management improvements.
- Use Quality Indicator scores as a leading operational metric.
- Evaluate queues in the context of workload complexity.
- Continue investing in agent development and training programs.

Project Conclusion

The analysis showed that operational execution factors such as handling time, SLA performance, escalations, service quality, and first-contact resolution have a stronger influence on customer outcomes than demographic segmentation variables.
